

TOWER AND BOOM STRUCTURE FOR LOADER BUCKET

Technical Field of the Invention

- 5 The invention relates to utility vehicles, particularly to utility tractors for industrial and agricultural use that incorporate a front loader bucket.

Background of the Invention

- Utility tractors include a front-mounted engine supported on a chassis
10 and located in front of the driver. The engine is covered by a hood. The hood has an inverted U-shaped cross-section and is closed on a front end by a grille and on a back end by a firewall. The firewall is covered by a fuel tank and a steering console. Utility tractors that incorporate a front loader bucket include a support structure to support and brace movement of the loader
15 bucket. The support structure includes two columns or towers arranged on opposite lateral sides of the fuel tank and steering console and extending substantially vertically, and a boom pivotally connected about a lateral axis to the towers at top ends of the towers. The boom is raised and lowered by a pair of hydraulic cylinders connected between the boom and towers.

- 20 The towers extend upwardly from the tractor chassis. The towers are spaced apart and located in the two spaces that are defined between the hood and the front wheels.

- The present inventors have recognized that if the towers and booms are arranged narrowly spaced apart, close to the hood, driver visibility to
25 observe the front axle and ground is impaired. The present inventors have recognized that this visibility is important because the front axle is typically the point of lowest ground clearance, the part that has the greatest chance of

striking an obstacle beneath the tractor. The present inventors have recognized that if the towers and boom arms are placed widely spaced apart, close to the front wheels, driver visibility to observe the outside edges of the loader bucket is impaired. The present inventors have recognized that this

5 visibility is important to allow precise finishing work by the loader bucket close to a structure without risking impact and damage to the structure. The present inventors have also recognized that it would be desirable to arrange the tractor hood to increase driver visibility to observe the top edge of the loader bucket. The present inventors have recognized that this visibility of the

10 top edge of the bucket is important to sense whether the bucket is full by observing material spill over the top edge of the bucket, and is important to sense the bucket elevation and levelness.

Summary of the Invention

15 The present invention provides a utility tractor having a front loader bucket, wherein the utility tractor has structural support components shaped to allow effective driver viewing of the front axle, the top of the bucket, and the side edges of the bucket.

Particularly, the tractor comprises shaped towers and boom arms that

20 support and brace the loader bucket for movement. The towers are connected to the tractor chassis at a relatively wide spacing and extend upwardly to a position at which the hydraulic cylinders that control bucket raising and lowering are attached. The towers then curve, angle, are tapered or are otherwise offset, inwardly and then extend upwardly substantially in

25 parallel to a point where the boom arms are connected to the towers.

The boom arms extend forwardly from their connection to the towers and then curve, angle, are tapered or are otherwise offset, outwardly to a wide spacing and then proceed forwardly substantially in parallel to the bucket connection. The tractor hood is sloped dramatically downwardly to allow improved visibility of the top of the bucket.

Because the hood is declined to a short front grille region, the grille region is wider to allow sufficient cooling area for the radiator. The boom arms are advantageously shaped to allow clearance for the wider hood at the grille.

The arrangement of the offset towers, offset boom arms and declined hood structure allows increased driver visibility to the front axle, increased driver visibility to side edges of the bucket, and increased driver visibility of the top edge of the bucket.

Numerous other advantages and features of the present invention will be become readily apparent from the following detailed description of the invention and the embodiments thereof, from the claims and from the accompanying drawings.

Brief Description of the Drawings

Figure 1 is an elevational view of a tractor incorporating the present invention;

Figure 2 is a top view of the tractor of Figure 1;

Figure 3 is perspective view of the tractor of Figure 1;

Figure 4 is an enlarged perspective view of the tractor of Figure 1 from a driver's view with portions of the tractor not shown for clarity;

Figure 5 is an enlarged perspective view of a portion of the tractor shown in Figure 4; and

Figure 6 is an enlarged schematical sectional view taken generally along lines 6-6 of Figure 2.

Detailed Description of the Preferred Embodiments

While this invention is susceptible of embodiment in many different forms, there are shown in the drawings, and will be described herein in detail, a specific embodiment thereof with the understanding that the present
10 disclosure is to be considered as an exemplification of the principles of the invention and is not intended to limit the invention to the specific embodiment illustrated.

Figures 1 through 3 illustrate a tractor 20 incorporating features of the present invention. The tractor 20 includes a chassis 24 supported on front
15 wheels 26 and larger rear wheels 28. The front wheels are carried on a front axle 27. A driver's seat 30 faces a steering console 32 that includes a steering wheel 34 and a fuel tank 38.

An engine (not visible in the Figures) is located forward of the steering console 32 beneath a hood 40. The hood 40 has a substantially U-shaped
20 cross-section, closed by the steering console 32 at a rear of the hood 40, and by a grille 42 (shown in Figure 2) at a front of the hood 40.

Sub
at
A loader bucket 52 is provided on a front of the tractor 20. The loader bucket 52 is supported on a boom comprising two symmetrical boom arms 58, 60. Substantially vertical towers 68, 70 have base ends 8a, 70a that are
25 curved inwardly to be fixed to the chassis 24, as shown in Figures 5 and 6.

The boom arms 58, 60 have base ends 58a, 60a that are pivotally connected on a lateral pivot axis 61 (shown in Figures 2 and 6) to distal ends 68b, 70b of the towers. The boom arms 58, 60 are pivotally connected at distal ends 58b, 60b to the bucket 52.

5 Hydraulic cylinders 78, 80 are pivotally attached between a mid-location 68c, 70c of each of the towers 68, 70 and a mid-location 58c, 60c of each of the respective boom arms 58, 60. Extension of the cylinders 78, 80 raises the distal ends 58b, 60b of the boom arms 58, 60, and retraction of the cylinders 78, 80 lowers the distal ends 58b, 60b of the boom arms 58, 60.

10 *sub av* As illustrated in Figure 6, the towers 68, 70 extend upwardly for a distance to the mid-location 68c, 70c connection of the hydraulic cylinders 78, 80 and then continue upwardly and are angled, curved, tapered or otherwise offset inwardly to the distal ends 68b, 70b of the towers at the connection of the boom arms 58, 60. The inward offset of the towers creates a recessed
15 outer, upper edge 68d, 70d that allows the operator to view the side edges of the bucket 52 from his seated position, with possibly only a small lateral movement of the operator's head.

In this regard, the boom arms 58, 60 extend rearward from the bucket 52 in a parallel fashion, widely spaced apart, to the mid-position 58c, 60c
20 where the cylinders 78, 80 are connected, and from that point are also curved, angled, are tapered or are otherwise offset, inwardly to the connection of the boom arms to the towers. The offset boom arms also enable an unobstructed view to the side edges 52a, 52b of the bucket 52.

sub av
25 As illustrated in Figures 4 and 5, the fuel tank 38 is mounted to cover a rear surface of the engine compartment and a rear surface of the towers 68,

10041833-101901

70 that substantially faces the driver. The fuel tank 38 is a complex shaped container that includes a central portion 38a and two wing portions 38b, 38c connected to the central portion 38c by upper and lower tube portions 38d, 38e and 38f, 38g, respectively. Gaps 80, 82 are formed between the wing portions 38b, 38c and the central portion 38a. These gaps 80, 82 coincide with lateral spaces 84, 86 (shown in Figure 6) formed between the hood 40 and the towers 68, 70 and allow an unobstructed downward oblique view of the utility vehicle axle 27 and the ground below. The wing portions 38b, 38c are tapered or otherwise contoured inwardly at sides thereof to match the inward offset of the towers 68, 70.

To additionally improve driver visibility, the hood 40 includes a top surface 86 that is steeply declined in a forward direction. The steep decline of the hood 40 allows an unobstructed driver view of a top edge 52c of the bucket when the tractor and the bucket are resting on level ground.

Because of the improved towers, boom, hood and fuel tank, an increased visibility of the bucket and ground below the tractor is achieved. This allows for close control of the tractor to move the bucket along a physical border or edge, such as to closely landscape an edge along a structure, or to control the bucket depth.

The dimensions for one example of a preferred embodiment of the present invention are as follows:

dimension

horizontal distance a from driver's eye 100 to top edge of hood

994 mm

horizontal distance b from top edge of hood to top

	edge of grill	1,012 mm
	horizontal distance <u>c</u> from top edge of grille to top	
	edge of bucket	1,037 mm
	vertical distance <u>d</u> from driver's eye to top edge of hood	551 mm
5	vertical distance <u>e</u> from top edge of hood to top edge	
	of grille	433 mm
	vertical distance <u>f</u> from driver's eye to top edge of	
	bucket	1,353 mm
	distance from <u>g</u> connection of boom to tower to	
10	inflection point of boom	995 mm
	horizontal clearance <u>h</u> between boom arms after inflection	
	point	778 mm
	horizontal clearance <u>i</u> between towers at distal ends	523 mm
	horizontal offset <u>j</u> of outer surface of towers	56 mm
15	vertical distance <u>k</u> between top of tower and midpoint	
	connection of hydraulic cylinder	450 mm
	vertical distance <u>l</u> between midpoint connection of	
	hydraulic cylinder and bottom of outer surface	478 mm

20 From the foregoing, it will be observed that numerous variations and modifications may be effected without departing from the spirit and scope of the invention. It is to be understood that no limitation with respect to the specific apparatus illustrated herein is intended or should be inferred. It is, of course, intended to cover by the appended claims all such modifications as

25 fall within the scope of the claims.
